Abstract

Let a physical body Ω in \mathbb{R}^2 or \mathbb{R}^3 be given. Assume that the electric conductivity distribution inside Ω consists of conductive inclusions in a known smooth background. Further, assume that a subset $\Gamma \subset \partial\Omega$ is available for boundary measurements. It is proved using hyperbolic geometry that certain information about the location of the inclusions can be exactly recovered from static electric measurements on Γ . More precisely: given a ball B with center outside the convex hull of Ω and satisfying $(\overline{B} \cap \partial\Omega) \subset \Gamma$, boundary measurements on Γ with explicitly given Dirichlet data are enough to determine whether or not B intersects the inclusion. An approximate detection algorithm is introduced based on the theory. Numerical experiments in dimension two with simulated noisy data suggest that the algorithm finds the inclusion-free domain near Γ and is robust against measurement noise. © 2000 Wiley Periodicals, Inc.

1 Introduction

1.1 Dirichlet-to-Neumann map

Let Ω be a bounded open set with smooth boundary in \mathbb{R}^d with $d = 2, 3$, and consider the following boundary value problem:

$$(1.1) \quad \begin{cases} \nabla \cdot (\gamma(x) \nabla v) &= 0 & \text{in } \Omega, \\ v &= f & \text{on } \partial\Omega. \end{cases}$$

Communications on Pure and Applied Mathematics, Vol. 000, 0001–0027 (2000)

© 2000 Wiley Periodicals, Inc.

We assume that $\gamma \in L^\infty(\Omega)$ and that $\gamma(x) \geq c > 0$ almost everywhere in Ω . Define the Dirichlet-to-Neumann (DN) map by

$$\Lambda : f \rightarrow \gamma(x) \left(\frac{\partial v}{\partial n} \right) \Big|_{\partial\Omega},$$

where v is the solution to (1.1) and n is the outer unit normal to $\partial\Omega$.

The inverse conductivity problem of Calderón [12] is to determine γ from Λ . This problem has several practical applications where γ represents the electric conductivity inside a physical body, v is the voltage potential, and Λ models static voltage-to-current measurements on the boundary of the body. The aim of electrical impedance tomography (EIT) is to form an image of the conductivity distribution from the knowledge of Λ . See [14, 8] for reviews of EIT.

When γ is smooth enough, it is well-known that one can reconstruct γ from the DN map, see Sylvester and Uhlmann [57], Nachman [49, 50] and Novikov [52]. In dimension two, the DN map determines $\gamma \in L^\infty(\Omega)$, as shown by Astala and Päiväranta [4].

The above-mentioned theorems guarantee the unique determination of γ from measurements on the whole surface of the body. However, it is often possible to measure only on part of the boundary. This is the case in medical and geophysical EIT since it is not practical to cover a patient or the Earth completely by electrodes. It is known in dimension three or higher, that if one knows the conductivity near the boundary one can reconstruct the conductivity from local voltage and current measurements [2]. This method seems to be difficult to implement numerically. In the general case, in dimension three or higher, it is shown in [41], that if one measures the voltage on an open subset of the boundary and measures the current flux in, roughly, the complement, one can determine uniquely the conductivity in the whole domain. There is no reconstruction procedure known at present for this result.

However, if we restrict ourselves to the anomaly detection problem, local measurements may be sufficient for obtaining crucial information about the conductivity. For example, cancerous breast tissue is known to differ significantly from healthy breast tissue in terms of conductivity [37]. Given local EIT data measured using electrodes placed on the breast, the problem is to find out whether there is a cancerous region (tumor) inside the breast, and if so, what is the approximate location of the tumor. See [59] and the references therein. Another relevant application of EIT is geophysical sensing for underground objects, see [36, 53, 54, 56].

We consider the problem of detection of inclusions in a two or three-dimensional body Ω from local boundary measurements. Let us assume that $\gamma(x)$ is a perturbation of known background conductivity $\gamma_0(x) \in C^\infty(\overline{\Omega})$. Namely, there exists an open subset $\Omega_1 \subset \Omega$ such that $\overline{\Omega}_1 \subset \Omega$ (this property is denoted by $\Omega_1 \subset\subset \Omega$) and

$$\gamma(x) = \begin{cases} \gamma_1(x), & x \in \Omega_1, \\ \gamma_0(x), & x \in \Omega_0 := \Omega \setminus \overline{\Omega}_1, \end{cases}$$

with $\gamma_1(x) \in L^\infty(\Omega)$ such that $\gamma(x) \geq c > 0$ almost everywhere in Ω . Let

$$\Lambda_0 : f \rightarrow \gamma_0 \left(\frac{\partial u}{\partial n} \right) \Big|_{\partial\Omega}, \quad \Lambda : f \rightarrow \gamma \left(\frac{\partial v}{\partial n} \right) \Big|_{\partial\Omega}$$

be the associated DN maps, where v is the solution to (1.1) and u solves equation (1.1) with γ replaced by γ_0 . We assume that $\gamma_0(x)$ is known on whole Ω and try to recover the location of Ω_1 from the local knowledge of Λ . We prove: let a ball B be given with center outside the convex hull of Ω and satisfying $(\overline{B} \cap \partial\Omega) \subset \Gamma$. Then boundary measurements on Γ with explicitly given Dirichlet data are enough to determine whether $(\overline{B} \cap \Omega_1) = \emptyset$ or not.

Let us briefly review existing theory on the inclusion detection problem. Unique determination from local boundary measurements has been studied by Isakov [31] and Ikehata [21, 25, 26]. Kohn and Vogelius show that piecewise analytic conductivities are uniquely determined by the DN map [42]. In some cases it is known that only one boundary measurement is sufficient to guarantee the uniqueness, see [16, 22, 24, 39, 44] and the references therein. The reconstruction method presented in this paper is different from these previous studies.

There are two main motivations for our paper. The first one is the paper [33] where in dimension 3 approximate complex geometrical optics solutions concentrated near hemispheres are constructed for the conductivity equation. The article [33] uses hyperbolic geometry as we do in this paper. The second one is the work of Ikehata [27]. Using the inequality of Kang-Seo-Sheen [40] and Mittag-Leffler's function from the theory of functions of one complex variable, he gave a method to find the location of inclusions in the two-dimensional case. The associated numerical computation is given in [30]. The crucial feature of Mittag-Leffler's function is that it grows up exponentially in some sector and decays polynomially in the complement of the sector. In this paper we aim at generalizing these results in dimensions 2 and 3, making use of hemispheres instead of sectors. Note that since we probe with hemispheres, we are to some extent able to recover concave parts of inclusions.

Let us briefly describe our mathematical ideas. We embed the conductivity problem (1.1) into hyperbolic space. The role of straight lines in two dimensions (planes in three dimensions) in the Euclidean geometry is replaced by circles (spheres) in the hyperbolic geometry. Using this property we can construct solutions of equation (1.1) that are exponentially growing (with respect to a parameter) in a ball and exponentially decaying in its complement. This explains the term *complex spherical waves* in the title.

1.2 Main theorems

Throughout the paper we shall assume that

$\gamma_1(x) - \gamma_0(x)$ has a constant sign on Ω_1 , and for any $p \in \Omega_1$, there exist constants $C, \varepsilon > 0$ such that

$$C^{-1} < |\gamma_1(x) - \gamma_0(x)| < C \quad \text{if} \quad |x - p| < \varepsilon.$$

Moreover $\partial\Omega_1$ is piecewise smooth.

Note that Ω_1 is an open set and that by the assumption, we have either $\gamma_1(x) > \gamma_0(x)$ on Ω_1 or $\gamma_1(x) < \gamma_0(x)$ on Ω_1 . Although our main purpose is to study discontinuous perturbations, we allow $\gamma(x)$ to be a continuous function. The inner product of $L^2(\partial\Omega)$ is denoted by $(\cdot, \cdot)_{\partial\Omega}$, the open ball with center x_0 and radius R is denoted by $B(x_0, R)$, and $\text{dis}(x, A)$ denotes the distance from the point x to the set A .

Theorem 1.1. *Take x_0 from the outside of the convex hull of Ω . Let $\varepsilon > 0$ be small enough so that $x_0 \notin U_\varepsilon :=$ the ε -neighborhood of the convex hull of Ω . Take an arbitrary constant $R > 0$. Then there exists $u_\tau(x) \in C^\infty(U_\varepsilon)$ depending on a large parameter $\tau > 0$ (and also on R) having the following properties.*

(1) u_τ satisfies the equation

$$\nabla \cdot (\gamma_0(x) \nabla u_\tau(x)) = 0 \quad \text{on } \Omega.$$

(2) Let K_\pm be any compact sets such that

$$K_+ \subset (U_\varepsilon \cap B(x_0, R)), \quad K_- \subset (U_\varepsilon \setminus \overline{B(x_0, R)}).$$

Then there exist constants $\delta > 0$ and $T > 0$ such that

$$\int_{K_+} |u_\tau(x)|^2 dx \geq e^{\delta\tau}, \quad \sup_{x \in K_-} |u_\tau(x)| \leq e^{-\delta\tau}, \quad \forall \tau > T.$$

(3) Let $f_\tau(x) = u_\tau|_{\partial\Omega}$. Then if $R < \text{dis}(x_0, \partial\Omega_1)$, there exist $\delta > 0$ and $T > 0$ such that if $\gamma_1(x) > \gamma_0(x)$ on Ω_1 ,

$$0 \leq ((\Lambda - \Lambda_0)f_\tau, f_\tau)_{\partial\Omega} < e^{-\delta\tau}, \quad \forall \tau > T,$$

and if $\gamma_1(x) < \gamma_0(x)$ on Ω_1 ,

$$0 \leq ((\Lambda_0 - \Lambda)f_\tau, f_\tau)_{\partial\Omega} < e^{-\delta\tau}, \quad \forall \tau > T.$$

(4) If $R > \text{dis}(x_0, \partial\Omega_1)$, there exist $\delta > 0$ and $T > 0$ such that if $\gamma_1(x) > \gamma_0(x)$ on Ω_1

$$((\Lambda - \Lambda_0)f_\tau, f_\tau)_{\partial\Omega} > e^{\delta\tau}, \quad \forall \tau > T,$$

and if $\gamma_1(x) < \gamma_0(x)$ on Ω_1

$$((\Lambda_0 - \Lambda)f_\tau, f_\tau)_{\partial\Omega} > e^{\delta\tau}, \quad \forall \tau > T.$$

In order to deal with the case $R = \text{dis}(x_0, \partial\Omega_1)$, we assume the following jump condition.

(1.2) For any $p \in \partial\Omega_1$, there exists $\varepsilon > 0$ such that $|\gamma_1(x) - \gamma_0(x)| > \varepsilon$ on $\Omega_1 \cap B(p, \varepsilon)$.

Theorem 1.2. *Let γ_0 and γ_1 satisfy (1.2). Take $R = \text{dis}(x_0, \partial\Omega_1)$. Let f_τ be as in Theorem 1.1. Then if $\gamma_1(x) > \gamma_0(x)$ on Ω_1 ,*

$$\liminf_{\tau \rightarrow \infty} \tau^{d-2} ((\Lambda - \Lambda_0)f_\tau, f_\tau)_{\partial\Omega} > 0,$$

and if $\gamma_1(x) < \gamma_0(x)$ on Ω_1 ,

$$\liminf_{\tau \rightarrow \infty} \tau^{d-2} ((\Lambda_0 - \Lambda)f_\tau, f_\tau)_{\partial\Omega} > 0.$$

It will be useful to give an approximate form of the above $f_\tau = u_\tau|_{\partial\Omega}$. In the 3-dimensional case, suppose that $\Omega \subset \subset \mathbb{R}_+^3 = \{x = (x_1, x_2, x_3); x_3 > 0\}$ and $x_0 = 0$. Then if $\gamma_0(x) = 1$, we have

$$(1.3) \quad u_\tau(x) \simeq \sqrt{\frac{y_3}{x_3}} e^{-\tau y_1 + i\tau y_3},$$

where

$$y_1 = \frac{x_1^2 + x_2^2 + x_3^2 - R^2}{(x_1 + R)^2 + x_2^2 + x_3^2}, \quad y_3 = \frac{2x_3 R}{(x_1 + R)^2 + x_2^2 + x_3^2}.$$

In the 2-dimensional case, suppose that $\Omega \subset \subset \mathbb{R}_+^2 = \{x = (x_1, x_2); x_2 > 0\}$, $x_0 = 0$, and $\gamma_0(x) = 1$. Then

$$(1.4) \quad u_\tau(x) \simeq e^{-\tau y_1 + i\tau y_2},$$

where

$$(1.5) \quad y_1 = \frac{x_1^2 + x_2^2 - R^2}{(x_1 + R)^2 + x_2^2}, \quad y_2 = \frac{2x_2 R}{(x_1 + R)^2 + x_2^2}.$$

1.3 Detection algorithm

Suppose that $\gamma_0 \equiv 1$. Then our detection algorithm in \mathbb{R}^d with $d = 2, 3$ is as follows.

- (i) Place the body Ω in the upper half space \mathbb{R}_+^d so that $\partial\Omega$ has a positive distance from $\{x \in \mathbb{R}^d; x_d = 0\}$.
- (ii) Draw a ball $B(0, R)$ such that $\overline{B(0, R)} \cap \partial\Omega \subset \Gamma$.
- (iii) For large $\tau > 0$, compute $I(\tau) = ((\Lambda - \Lambda_0)f_\tau, f_\tau)_{\partial\Omega}$.
- (iv) If $I(\tau) \rightarrow 0$ as $\tau \rightarrow \infty$, we infer that $B(0, R)$ does not intersect the inclusion.
- (v) If $I(\tau) \rightarrow \infty$ (or $-\infty$) as $\tau \rightarrow \infty$, we infer that $B(0, R)$ intersects the inclusion and $\gamma_1(x) > \gamma_0(x)$ (or $\gamma_1(x) < \gamma_0(x)$) on it.

In practical situations it is not possible to compute the limit $\tau \rightarrow \infty$ since measurement noise and the discrete nature of electrode data restrict τ to small values only. Inspired by the decay and growth estimates in claims (3) and (4) of Theorem 1.1 we suggest using only two finite values for τ . We replace steps (iii), (iv) and (v) of the above algorithm by the following steps:

- (iii)' Take $\tau_1 < \tau_2$ and compute the corresponding inner products

$$I_1 := ((\Lambda - \Lambda_0)f_{\tau_1}, f_{\tau_1})_{\partial\Omega} \quad \text{and} \quad I_2 := ((\Lambda - \Lambda_0)f_{\tau_2}, f_{\tau_2})_{\partial\Omega}.$$

Actually, we replace f_τ by its approximate form given in (1.3) or (1.4).

- (iv)' If $I_1 \geq I_2 > 0$ or $I_1 \leq I_2 < 0$, we infer that $B(0, R)$ does not intersect the inclusion.

(v)' If $I_2 > I_1 > 0$ (or $I_2 < I_1 < 0$), we infer that $B(0, R)$ intersects the inclusion and $\gamma_1(x) > \gamma_0(x)$ (or $\gamma_1(x) < \gamma_0(x)$) on it.

Of course, steps (iii)', (iv)' and (v)' give only approximate information whereas steps (iii), (iv) and (v) hold exactly. However, the necessity of using the modified steps is a consequence of the inherent ill-posedness of the inverse conductivity problem. Note that our algorithm does not involve the solution of any direct problem, so it is computationally effective.

In our numerical computation we use boundary data g_τ such that $g_\tau = f_\tau$ on Γ and $g_\tau = 0$ on $\partial\Omega \setminus \Gamma$. This choice leads to approximately correct results due to the exponential decay in τ of f_τ outside Γ . Theoretically it is desirable to prove the assertions (3) and (4) of Theorem 1.1 with f_τ replaced by $\chi_\varepsilon(x)f_\tau(x)$, where $\chi_\varepsilon(x) \in C_0^\infty(\mathbb{R}^d)$ satisfies $\chi_\varepsilon(x) = 1$ on $B(x_0, R + \varepsilon/2)$ and $\chi_\varepsilon(x) = 0$ on $\mathbb{R}^d \setminus B(x_0, R + \varepsilon)$ with small $\varepsilon > 0$. However for the moment we can prove it only when $\gamma \in C(\overline{\Omega})$ (see Theorem 2.7).

We can slightly improve our results. *Even if we do not assume the constant sign of $\gamma_1(x) - \gamma_0(x)$ globally on Ω_1* , we can conclude the exponential decay of $|((\Lambda - \Lambda_0)f_\tau, f_\tau)|$ when $R < \text{dis}(x_0, \partial\Omega_1)$. To get a sharper information of $\text{dis}(x_0, \partial\Omega)$, the following *local assumption* on the sign is sufficient. Let $\mathcal{P}(x_0)$ be the set of points on $\partial\Omega_1$ where $B(x_0, R)$ first touches $\partial\Omega_1$. If there exists $\varepsilon > 0$ such that $\gamma_1(x) - \gamma_0(x)$ has a constant sign on $\Omega_1 \cap \mathcal{P}_\varepsilon(x_0)$, where $\mathcal{P}_\varepsilon(x_0)$ is the ε -neighborhood of $\mathcal{P}(x_0)$, our detection algorithm works in the following way. If R is greater than but is very close to $\text{dis}(x_0, \partial\Omega_1)$, Theorem 1.1 (4) and Theorem 1.2 still hold. For instance, if $\gamma_1(x) - \gamma_0(x)$ has a constant sign on each connected component of Ω_1 , and if we know that $B(x_0, R)$ touches only one of these components, our algorithm works.

In dimension two, numerical detection of inclusions and other anomalies from measurements on the whole boundary has been discussed in [3, 6, 9, 10, 11, 13, 15, 17, 18, 19, 28, 29, 30, 34, 38, 43, 44, 45]. While some of these algorithms may be modified to accept localized data, the present paper is the first to numerically demonstrate the recovery of two-dimensional electrical inclusions from localized measurements. We remark that a numerical algorithm for recovering the conductivity at the boundary from localized measurements is considered in [51]. In dimension three, reconstruction of features of conductivity from localized EIT measurements is studied in [1, 7, 35, 47, 48, 58]. This paper presents a novel inclusion detection method for 3D EIT.

Our approach is independent of previous numerical works apart from the following connection. The harmonic function $\exp(i\tau(y_2 + iy_1))$ in (1.4) (introduced in the context of inverse conductivity problem already by Calderón in [12]) was used by Ikehata in [23] to prove that the convex hull of inclusion can be recovered from the DN map. Ikehata's method was implemented numerically in [29] and [10] simultaneously and independently.

1.4 Plan of paper

We give the proofs of our theoretical results in section 2 and present a computational method based on the theory in section 3. We test our detection algorithm in several two-dimensional situations using simulated noisy data in section 4. We conclude our results in section 5. In appendix A we present elementary derivation of exact DN maps for a constant background and a layered medium; these results are used to validate our simulated data.

2 Proof of main theorems

2.1 Reduction to the Schrödinger equation.

Suppose u satisfies the conductivity equation

$$\begin{cases} \nabla \cdot (\gamma_0(x) \nabla u) &= 0 & \text{in } \Omega, \\ u &= f & \text{on } \partial\Omega, \end{cases}$$

with the associated DN map

$$\Lambda_0 f = \gamma_0(n \cdot \nabla)u \Big|_{\partial\Omega}.$$

Then $u' = \sqrt{\gamma_0}u$ satisfies

$$(2.1) \quad \begin{cases} (-\Delta + q_0(x))u' = 0 & \text{in } \Omega, & q_0(x) = \frac{\Delta \sqrt{\gamma_0(x)}}{\sqrt{\gamma_0(x)}} \\ u' = f' := \sqrt{\gamma_0}f & \text{on } \partial\Omega \end{cases}$$

with the associated DN map

$$\Lambda_{01} f' = (n \cdot \nabla)u' \Big|_{\partial\Omega}.$$

The DN maps are related as follows:

$$\Lambda_{01} = \frac{1}{\sqrt{\gamma_0}} \Lambda_0 \frac{1}{\sqrt{\gamma_0}} + \frac{(n \cdot \nabla) \sqrt{\gamma_0}}{\sqrt{\gamma_0}}.$$

2.2 Hyperbolic space

Let \mathbb{H}^d be the d -dimensional hyperbolic space realized in the upper-half space. Namely $\mathbb{H}^d = \mathbb{R}_+^d = \{(x, x_d); x \in \mathbb{R}^{d-1}, x_d > 0\}$ equipped with the Riemannian metric

$$ds^2 = (x_d)^{-2}((dx)^2 + (dx_d)^2).$$

The Laplace-Beltrami operator Δ_g on \mathbb{H}^d is defined by

$$\Delta_g = x_d^2 \partial_d^2 - (d-2)x_d \partial_d + x_d^2 \Delta_x,$$

where $\partial_d = \partial/\partial x_d$ and Δ_x is the Euclidean Laplacian on \mathbb{R}^{d-1} .

2.3 Embedding to \mathbb{H}^3

The main idea of the proof of Theorem 1.1 is to embed the Dirichlet problem (2.1) to the hyperbolic space \mathbb{H}^d . Let us begin with the 3-dimensional case. Without loss of generality, we assume that $x_0 = 0$ and that

$$\Omega \subset \subset \mathbb{R}_+^3 = \{(x, x_3) \in \mathbb{R}^3; x \in \mathbb{R}^2, x_3 > 0\}.$$

For a solution u' to the equation (2.1), we put $u'' = \sqrt{x_3}u'$. Then

$$(2.2) \quad \begin{cases} (-\Delta_g + x_3^2 q_0(x) - \frac{3}{4})u'' = 0 & \text{in } \Omega, \\ u'' = f'' := \sqrt{x_3} \gamma_0 f & \text{on } \partial\Omega, \end{cases}$$

where $\Delta_g = x_3^2 \partial_3^2 - x_3 \partial_3 + x_3^2 \Delta_x$ is the Laplace-Beltrami operator on \mathbb{H}^3 . The associated DN map is defined by

$$\Lambda_{02} f'' = x_3 (n \cdot \nabla) u'' \Big|_{\partial\Omega},$$

where n is the outer unit normal to $\partial\Omega$ with respect to the Euclidean metric $(dx)^2 + (dx_3)^2$ and ∇ is the Euclidean gradient. Therefore

$$\Lambda_{02} = x_3 \sqrt{x_3} \Lambda_{01} \frac{1}{\sqrt{x_3}} + \sqrt{x_3} (n \cdot \nabla) \sqrt{x_3}.$$

2.4 Hyperbolic isometry on \mathbb{H}^3

We are going to detect inclusions inside the sphere of radius R centered at the origin, which is denoted by $S(0, R)$. We transform this sphere to a plane using hyperbolic isometry. We represent $(x_1, x_2, x_3) \in \mathbb{R}_+^3 = \mathbb{H}^3$ by quaternions: $\mathbf{z} = x_1 \mathbf{1} + x_2 \mathbf{i} + x_3 \mathbf{j}$. Let us recall the representation of \mathbf{z} by a 2×2 matrix:

$$(2.3) \quad \mathbf{z} = x_1 \mathbf{1} + x_2 \mathbf{i} + x_3 \mathbf{j} = \begin{pmatrix} x_1 + ix_3 & x_2 \\ -x_2 & x_1 - ix_3 \end{pmatrix}.$$

It is well-known that for $\beta = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL(2, \mathbf{C})$, the transformation

$$(2.4) \quad \mathbf{z} \mapsto \beta \cdot \mathbf{z} = (a\mathbf{z} + b)(c\mathbf{z} + d)^{-1}$$

is an isometry on \mathbb{H}^3 . When $x_3 = 0$, this is a linear fractional transformation on $\mathbb{R}^2 \times \{0\} \simeq \mathbf{C}$. We choose β in such a way that this induced transformation maps the circle $S(0, R) \cap \{x_3 = 0\}$ to the line $x_1 = x_3 = 0$, i.e.

$$\beta = \begin{pmatrix} 1/\sqrt{2R} & -\sqrt{R/2} \\ 1/\sqrt{2R} & \sqrt{R/2} \end{pmatrix}.$$

Then by the transformation (2.4), $S(0, R) \cap \{x_3 > 0\}$ is mapped to the semi-plane $\{x_1 = 0, x_3 > 0\}$. We show these facts by a direct computation.

Lemma 2.1. *The map $x \rightarrow y$ defined by*

$$\mathbf{w} = (\mathbf{z} - R\mathbf{1})(\mathbf{z} + R\mathbf{1})^{-1} = y_1\mathbf{1} + y_2\mathbf{i} + y_3\mathbf{j}$$

is an isometry on \mathbb{H}^3 , which maps

- (1) *the hemisphere $S(0, R) \cap \{x_3 > 0\}$ to the semi-plane $\{y_1 = 0, y_3 > 0\}$,*
- (2) *the half-ball $B(0, R) \cap \{x_3 > 0\}$ to the quarter region $\{y_1 < 0, y_3 > 0\}$,*
- (3) *the semi-plane $\{x_2 = 0, x_3 > 0\}$ to the semi-plane $\{y_2 = 0, y_3 > 0\}$.*

Proof. The following maps are isometries on \mathbb{H}^d :

- dilation: $(x, x_d) \rightarrow (\lambda x, \lambda x_d)$, $\lambda > 0$,
- translation: $(x, x_d) \rightarrow (x + x', x_d)$, $x' \in \mathbb{R}^{d-1}$,
- rotation: $(x, x_d) \rightarrow (Rx, x_d)$, $R \in O(d-1)$,
- inversion with respect to the sphere orthogonal to $\{x_d = 0\}$: $(x, x_d) \rightarrow (x/r^2, x_d/r^2)$, $r^2 = |x|^2 + x_d^2$.

By (2.3) and (2.4) we have

$$(2.5) \quad \begin{cases} y_1 = \frac{x_1^2 + x_2^2 + x_3^2 - R^2}{(x_1 + R)^2 + x_2^2 + x_3^2}, \\ y_2 = \frac{2x_2R}{(x_1 + R)^2 + x_2^2 + x_3^2}, \\ y_3 = \frac{2x_3R}{(x_1 + R)^2 + x_2^2 + x_3^2}, \end{cases}$$

which then implies the lemma by a straightforward computation. Let us note that the inverse transform

$$\mathbf{z} = R(\mathbf{w} + \mathbf{1})(-\mathbf{w} + \mathbf{1})^{-1}$$

is given by

$$\begin{cases} x_1 = R \frac{1 - y_1^2 - y_2^2 - y_3^2}{(y_1 - 1)^2 + y_2^2 + y_3^2}, \\ x_2 = R \frac{2y_2}{(y_1 - 1)^2 + y_2^2 + y_3^2}, \\ x_3 = R \frac{2y_3}{(y_1 - 1)^2 + y_2^2 + y_3^2}. \end{cases}$$

□

2.5 Embedding to \mathbb{H}^2

The embedding of the 2-dimensional problem is much simpler than the 3-dimensional case. Suppose u' satisfies in dimension two the equation

$$(-\Delta + q)u' = 0 \quad \text{in } \Omega.$$

Then multiplying by x_2^2 , we get

$$(2.6) \quad (-x_2^2 \Delta + x_2^2 q) u' = 0 \quad \text{in } \Omega.$$

This is just the Schrödinger equation on \mathbb{H}^2 .

2.6 Hyperbolic isometry on \mathbb{H}^2

In the 2-dimensional case, the above hyperbolic isometry is the usual linear fractional transformation.

Lemma 2.2. *The map $x \rightarrow y$ defined by*

$$y_1 + iy_2 = \frac{(x_1 + ix_2) - R}{(x_1 + ix_2) + R}$$

is an isometry on \mathbb{H}^2 , which maps

- (1) *the hemi-circle $\{|x| = R, x_2 > 0\}$ to the half-line $\{y_1 = 0, y_2 > 0\}$,*
- (2) *the half-disc $\{|x| < R, x_2 > 0\}$ to the quarter space $\{y_1 < 0, y_2 > 0\}$.*

Proof. Recall that y_1 and y_2 are given by (1.5). The inverse transform is

$$x_1 = R \frac{1 - y_1^2 - y_2^2}{(y_1 - 1)^2 + y_2^2}, \quad x_2 = R \frac{2y_2}{(y_1 - 1)^2 + y_2^2}.$$

□

Let u^* and Λ_{02}^* be u and Λ_{02} transformed by these isometries. Then the equations (2.2) and (2.6) are invariant. One should keep in mind that now one uses the new rectangular coordinates x^* and the new Euclidean outer unit normal n^* with respect to the new coordinate system. We use the same notation Ω, x, n , respectively, for the transformed domain, the new variables and the new unit normal.

2.7 Trial functions

First let us recall the notion of complex geometrical optics solutions of the Schrödinger equation in \mathbb{R}^d .

For $s \in \mathbb{R}$, let $L^{2,s}$ be the weighted L^2 -space defined by

$$f \in L^{2,s} \iff \int_{\mathbb{R}^d} (1 + |x|)^{2s} |f(x)|^2 dx = \|f\|_s^2 < \infty.$$

For $\zeta \in \mathbb{C}^d$ such that $\zeta^2 = \sum_{i=1}^d \zeta_i^2 = 0$, we define

$$G_0(\zeta)f = (2\pi)^{-d/2} \int_{\mathbb{R}^d} \frac{e^{ix \cdot \xi}}{\xi^2 + 2\zeta \cdot \xi} \widehat{f}(\xi) d\xi,$$

$\widehat{f}(\xi)$ being the Fourier transform of f . Then for $s > 1/2$, there exists a constant $C_s > 0$ such that

$$(2.7) \quad \|\partial_x^\alpha G_0(\zeta)f\|_{-s} \leq C_s |\zeta|^{|\alpha|-1} \|f\|_s, \quad |\zeta| > C_s, \quad |\alpha| \leq 1.$$

See [49, 57]. For a bounded function of compact support $q(x)$, we define

$$G_q(\zeta) = (1 + G_0(\zeta)q)^{-1}G_0(\zeta).$$

Then $G_q(\zeta)$ also satisfies (2.7). We put

$$(2.8) \quad w(\zeta) = e^{ix \cdot \zeta} - e^{ix \cdot \zeta} G_q(\zeta)q \cdot 1.$$

It has the following property.

Lemma 2.3. *Let w be as in (2.8). It satisfies:*

(1) $(-\Delta + q)w(\zeta) = 0$ on \mathbb{R}^d .

(2) For any compact set D in \mathbb{R}^d , we have

$$\|\partial_x^\alpha (e^{-ix \cdot \zeta} w(\zeta))\|_{L^2(D)} \leq C|\zeta|^{|\alpha|-1} \quad \text{if } |\alpha| \leq 1.$$

Now we construct our trial function in the hyperbolic space. Let us denote

$$y = x_3, \quad x = (x_1, x_2) \quad \text{for } d = 3,$$

$$y = x_2, \quad x = x_1 \quad \text{for } d = 2.$$

We write $\zeta = (i\tau, 0, \dots, 0, \tau)$ and define

$$U(\tau) = x_d^{(d-2)/2} w(\zeta).$$

Lemma 2.4. *The function $U(\tau)$ defined above has the following properties.*

(1) $(-y^2 \Delta_{x,y} + (d-2)y \partial_y + V_0(x, y) - E_d)U(\tau) = 0$ on Ω , where $V_0(x, y) = y^2 q(x, y)$ and $E_d = d(d-2)/4$.

(2) Let K_\pm be any compact sets such that

$$K_- \subset \mathbb{R}_+^d \cup \{x_1 > 0\}, \quad K_+ \subset \mathbb{R}_+^d \cup \{x_1 < 0\}.$$

Then we have for some $\delta > 0$

$$(2.9) \quad \sum_{|\beta| \leq 1} |\partial_{x,y}^\beta U(\tau)| \leq e^{-\delta \tau} \quad \text{on } K_-,$$

$$(2.10) \quad \sum_{|\beta| \leq 1} \int_{K_+} |\partial_{x,y}^\beta U(\tau)|^2 dx dy \geq e^{\delta \tau}.$$

Proof. The assertion (1) follows from Lemma 2.3. By our construction

$$(2.11) \quad U(\tau) = y^{(d-2)/2} e^{-\tau x_1 + i\tau y} (1 + g(\tau)),$$

where $g(\tau)$ satisfies

$$\|\partial_{x,y}^\beta g(\tau)\|_{L^2(K)} = O(\tau^{|\beta|-1})$$

on any compact set $K \subset \mathbb{R}_+^d$. These facts prove (2.9) and (2.10). \square

As will be explained in the proof of Theorem 1.1, the asymptotic form of $u_\tau(x)$ in (1.3) follows from (2.11). If one needs a better expansion, one should take into account the Green operator $G_0(\zeta)$. Alternatively, one can use the Green operator in the hyperbolic space, as was done in [32] or [33].

2.8 Proof of Theorem 1.1

We use the notation

$$(\psi, v)_\Omega = \int_\Omega \psi \bar{v} dx dy, \quad (f, g)_{\partial\Omega} = \int_{\partial\Omega} f \bar{g} dS,$$

where dS is the measure on $\partial\Omega$ induced from the Euclidean metric. First we recall the meaning of the solution of the equation (1.1). Let

$$[\psi]_{\partial\Omega_1} = \text{tr}_+ \psi - \text{tr}_- \psi$$

be the jump of the function ψ across $\partial\Omega_1$, where tr_+ and tr_- denote the trace of ψ on $\partial\Omega_1$ from the side of Ω_1 and Ω_0 , respectively. For $f \in H^{3/2}(\partial\Omega)$, we put

$$\mathcal{A}_f = \left\{ \psi \in H^2(\Omega_0) \oplus H^2(\Omega_1) \mid \psi = f \text{ on } \partial\Omega, [\psi]_{\partial\Omega_1} = 0, \left[\gamma \frac{\partial \psi}{\partial n} \right]_{\partial\Omega_1} = 0 \right\}.$$

By the solution of (1.1), we mean $v \in \mathcal{A}_f$ satisfying the equation $\nabla \cdot (\gamma(x) \nabla v(x)) = 0$ in $\Omega_0 \cup \Omega_1$. The existence of v follows from standard variational arguments and the uniqueness is an immediate consequence of the formula $(\gamma \partial v / \partial n, v)_{\partial\Omega} = (\gamma \nabla v, \nabla v)_\Omega$. This formula in particular implies the following lemma.

Lemma 2.5.

$$(\Lambda f, f)_{\partial\Omega} = \inf_{\psi \in \mathcal{A}_f} (\gamma \nabla \psi, \nabla \psi)_\Omega.$$

Our starting points are the following inequalities given in [40] (see also [20]).

Lemma 2.6. *Let $f \in H^{3/2}(\partial\Omega)$, and u be a solution to the boundary value problem*

$$\begin{cases} \nabla \cdot (\gamma_0(x) \nabla u) = 0 & \text{in } \Omega, \\ u = f & \text{on } \partial\Omega. \end{cases}$$

Then for any positive $\gamma(x)$ and $\gamma_0(x)$, we have

$$(2.12) \quad ((\Lambda - \Lambda_0)f, f)_{\partial\Omega} \leq ((\gamma - \gamma_0) \nabla u, \nabla u)_\Omega,$$

$$(2.13) \quad \left(\frac{\gamma_0}{\gamma} (\gamma - \gamma_0) \nabla u, \nabla u \right)_\Omega \leq ((\Lambda - \Lambda_0)f, f)_{\partial\Omega}.$$

Proof. Let v be a solution to (1.1). By Green's formula, we have for $\varphi = v$ and u

$$(2.14) \quad \left(\gamma \frac{\partial v}{\partial n}, \varphi \right)_{\partial\Omega} = (\gamma \nabla v, \nabla \varphi)_\Omega,$$

$$(2.15) \quad \left(\gamma_0 \frac{\partial u}{\partial n}, \varphi \right)_{\partial\Omega} = (\gamma_0 \nabla u, \nabla \varphi)_\Omega.$$

Since $v = u = f$ on $\partial\Omega$, we then have by (2.14) and (2.15)

$$(2.16) \quad \begin{aligned} (\gamma \nabla v, \nabla v)_\Omega &= (\gamma \nabla v, \nabla u)_\Omega, \\ (\gamma_0 \nabla u, \nabla v)_\Omega &= (\gamma_0 \nabla u, \nabla u)_\Omega. \end{aligned}$$

Let us derive the following two formulas :

$$(2.17) \quad (\gamma \nabla(v-u), \nabla(v-u))_{\Omega} + ((\gamma_0 - \gamma) \nabla u, \nabla u)_{\Omega} = ((\Lambda_0 - \Lambda)f, f)_{\partial\Omega},$$

$$(2.18) \quad (\gamma_0 \nabla(v-u), \nabla(v-u))_{\Omega} + ((\gamma - \gamma_0) \nabla v, \nabla v)_{\Omega} = ((\Lambda - \Lambda_0)f, f)_{\partial\Omega}.$$

In fact, using (2.16) we have

$$\begin{aligned} & (\gamma \nabla(v-u), \nabla(v-u))_{\Omega} \\ &= -(\gamma \nabla u, \nabla v)_{\Omega} + (\gamma_0 \nabla u, \nabla u)_{\Omega} + ((\gamma - \gamma_0) \nabla u, \nabla u)_{\Omega} \\ &= -(\Lambda f, f)_{\partial\Omega} + (\Lambda_0 f, f)_{\partial\Omega} + ((\gamma - \gamma_0) \nabla u, \nabla u)_{\Omega}, \end{aligned}$$

where in the second line we have used (2.14) and (2.15) with $\varphi = u$. This proves (2.17). The equality (2.18) is proven similarly.

Obviously, (2.17) implies (2.12). By completing the square we have

$$\begin{aligned} & \gamma_0 |\nabla(v-u)|^2 + (\gamma - \gamma_0) |\nabla v|^2 \\ &= \gamma \left| \nabla v - \frac{\gamma_0}{\gamma} \nabla u \right|^2 + \frac{\gamma_0}{\gamma} (\gamma - \gamma_0) |\nabla u|^2 \\ &\geq \frac{\gamma_0}{\gamma} (\gamma - \gamma_0) |\nabla u|^2, \end{aligned}$$

which together with (2.18) implies (2.13). \square

Let us note that Lemma 2.6 holds regardless of the sign of $\gamma(x) - \gamma_0(x)$.

Proof of Theorem 1.1. We prove the theorem in the case that $\gamma_1(x) > \gamma_0(x)$ on Ω_1 . The other case is proved in a similar way. Let $d = 3$. We take x_0 from the outside of the convex hull of Ω . Without loss of generality, we assume that $x_0 = 0$, $\Omega \subset \subset \mathbb{R}_+^3$. Let $S(0, R)$ be the sphere of radius R with center at the origin. By using Lemma 2.1, we map the hemisphere $S(0, R) \cap \{x_3 > 0\}$ to the semi-plane $\{y_1 = 0, y_3 > 0\}$ so that the half-ball $\{|x| < R, x_3 > 0\}$ is mapped to the region $\{y_1 < 0, y_3 > 0\}$. Now we follow the procedures given in sections 2.1, 2.3, 2.4 and 2.7:

$$u \rightarrow u' = \sqrt{\gamma_0} u \rightarrow u'' = \sqrt{x_3} u' \rightarrow (u'')^*(y) = u''(x).$$

This final $(u'')^*(y)$ satisfies the equation

$$\begin{cases} (-\Delta_g + V(y))(u'')^* = 0, \\ V(y) = x_3^2 q_0(x) - \frac{3}{4}. \end{cases}$$

We construct the solution $U(\tau)$ of this equation by Lemma 2.4. Transforming back, we put

$$u_{\tau}(x) = (\gamma_0(x)x_3)^{-1/2} U(\tau, y_1, y_2, y_3),$$

where y_1, y_2, y_3 are given by (2.5). Then u_{τ} solves the equation $\nabla \cdot (\gamma_0(x) \nabla u_{\tau}) = 0$.

Note that u_{τ} is exponentially increasing in $\Omega \cap \{|x| < R\}$ and exponentially decreasing in $\Omega \cap \{|x| > R\}$. Let $f_{\tau} = u_{\tau}|_{\partial\Omega}$. Then by Lemma 2.6, the behavior of $((\Lambda - \Lambda_0)f_{\tau}, f_{\tau})$ is controlled by $\|\nabla u_{\tau}\|_{L^2(\Omega_1)}$, which is exponentially decreasing or increasing accordingly as $\{|x| < R\} \cap \Omega_1 = \emptyset$, or $\{|x| < R\} \cap \Omega_1 \neq \emptyset$. This

proves Theorem 1.1 for $d = 3$. The two-dimensional case is proved in a similar manner. \square

2.9 Proof of Theorem 1.2

Proof of Theorem 1.2. As above we prove the case that $\mathfrak{H}(x) > \mathfrak{H}_0(x)$ on Ω_1 . We first consider the 3-dimensional case. Assume that the sphere $S(0, R)$ touches $\partial\Omega$ at p . By the use of hyperbolic isometry as in the proof of Theorem 1.1, one can assume that $p = (0, 0, p_3)$ and $\Omega_1 \subset \{x_1 > 0\}$ so that $u_\tau(x)$ behaves like $a(x)e^{-\tau x_1 + i\tau x_3}$ near p , where $a(x) \in C^\infty$. Let us note that the condition (1.2) is invariant by hyperbolic isometries. One can then take an open cone C_p with small positive opening and vertex p such that $C_p \subset \Omega_1$. The area of the section $C_p \cap \{x_1 = t\}$ is Ct^2 with a constant $C > 0$. We then have for some constant $\delta > 0$

$$\|\nabla u_\tau\|_{L^2(C_p)}^2 \geq C\tau^2 \int_0^\delta e^{-2\tau x_1} x_1^2 dx_1 = \frac{C}{\tau} \int_0^{\tau\delta} e^{-2y} y^2 dy.$$

By using (2.13) and (1.2), we then have

$$((\Lambda - \Lambda_0)f_\tau, f_\tau) \geq C\|\nabla u_\tau\|_{L^2(C_p)}^2 \geq \frac{C}{\tau} \int_0^{\tau\delta} e^{-2y} y^2 dy.$$

Theorem 1.2 then follows immediately. The 2-dimensional case is proved similarly. \square

2.10 Localized measurements

We end this section by the following theorem.

Theorem 2.7. *Suppose $\gamma(x) \in C(\overline{\Omega})$. For a sufficiently small $\varepsilon > 0$, let $\chi_\varepsilon(x) \in C_0^\infty(\mathbf{R}^d)$ be such that $\chi_\varepsilon(x) = 1$ on $B(x_0, R + \varepsilon/2)$, and $\chi_\varepsilon(x) = 0$ on $\mathbf{R}^d \setminus B(x_0, R + \varepsilon)$. We define $f_\tau^{(\infty)}(x) = \chi_\varepsilon(x)f_\tau(x)$. Then Theorem 1.1 (3) and (4) as well as Theorem 1.2 hold with f_τ replaced by $f_\tau^{(\infty)}$.*

Proof. We prove the case that $\mathfrak{H}(x) > \mathfrak{H}_0(x)$ on Ω_1 . Since $\gamma(x) \in C(\overline{\Omega})$, Lemma 2.5 holds with \mathcal{A}_f replaced by

$$\mathcal{A}'_f = \{\psi \in H^1(\Omega); \psi = f \text{ on } \partial\Omega\}.$$

Note that \mathcal{A}'_f does not depend on γ . Since $\mathfrak{H}_0 \leq \gamma$, Lemma 2.5 implies $(\Lambda_0 f, f) \leq (\Lambda f, f)$. Let $T = \Lambda - \Lambda_0$ and define $f_\tau^{(0)} = f_\tau - f_\tau^{(\infty)}$. Expanding

$$(T(\varepsilon f_\tau^{(\infty)} \pm \varepsilon^{-1} f_\tau^{(0)}), \varepsilon f_\tau^{(\infty)} \pm \varepsilon^{-1} f_\tau^{(0)}) \geq 0,$$

we have

$$\left| (T f_\tau^{(\infty)}, f_\tau^{(0)}) + (T f_\tau^{(0)}, f_\tau^{(\infty)}) \right| \leq \varepsilon^2 (T f_\tau^{(\infty)}, f_\tau^{(\infty)}) + \varepsilon^{-2} (T f_\tau^{(0)}, f_\tau^{(0)}).$$

Adding two (in)equalities

$$(T f_\tau^{(\infty)}, f_\tau^{(\infty)}) + (T f_\tau^{(0)}, f_\tau^{(0)}) + (T f_\tau^{(\infty)}, f_\tau^{(0)}) + (T f_\tau^{(0)}, f_\tau^{(\infty)}) = (T f_\tau, f_\tau),$$

$$-(Tf_\tau^{(\infty)}, f_\tau^{(0)}) - (Tf_\tau^{(0)}, f_\tau^{(\infty)}) \leq \varepsilon^2 (Tf_\tau^{(\infty)}, f_\tau^{(\infty)}) + \varepsilon^{-2} (Tf_\tau^{(0)}, f_\tau^{(0)}),$$

we then have

$$(2.19) \quad (1 - \varepsilon^2)(Tf_\tau^{(\infty)}, f_\tau^{(\infty)}) \leq (Tf_\tau, f_\tau) + (\varepsilon^{-2} - 1)(Tf_\tau^{(0)}, f_\tau^{(0)}).$$

Adding

$$(Tf_\tau^{(\infty)}, f_\tau^{(\infty)}) + (Tf_\tau^{(0)}, f_\tau^{(0)}) + (Tf_\tau^{(\infty)}, f_\tau^{(0)}) + (Tf_\tau^{(0)}, f_\tau^{(\infty)}) = (Tf_\tau, f_\tau),$$

$$-(Tf_\tau^{(\infty)}, f_\tau^{(0)}) - (Tf_\tau^{(0)}, f_\tau^{(\infty)}) \geq -\varepsilon^2 (Tf_\tau^{(\infty)}, f_\tau^{(\infty)}) - \varepsilon^{-2} (Tf_\tau^{(0)}, f_\tau^{(0)}),$$

we also have

$$(2.20) \quad (1 + \varepsilon^2)(Tf_\tau^{(\infty)}, f_\tau^{(\infty)}) + (1 + \varepsilon^{-2})(Tf_\tau^{(0)}, f_\tau^{(0)}) \geq (Tf_\tau, f_\tau).$$

Let $u_\tau^{(0)} = (1 - \chi_\varepsilon(x))u_\tau$. Then $u_\tau^{(0)} \in \mathcal{A}'_{f_\tau^{(0)}}$, hence by Lemma 2.5

$$(\Lambda f_\tau^{(0)}, f_\tau^{(0)})_{\partial\Omega} \leq (\gamma \nabla u_\tau^{(0)}, \nabla u_\tau^{(0)})_\Omega.$$

By Theorem 1.1 (2), the right-hand side is exponentially decreasing in τ . Replacing γ by γ_0 , we also have that $(\Lambda_0 f_\tau^{(0)}, f_\tau^{(0)})$ is exponentially decreasing. Therefore for some $\delta > 0$,

$$(2.21) \quad |(Tf_\tau^{(0)}, f_\tau^{(0)})| \leq C e^{-\delta\tau}.$$

Suppose $R < \text{dis}(x_0, \partial\Omega)$. Then in view of Theorem 1.1 (3), (2.19) and (2.21), we see that $(Tf_\tau^{(\infty)}, f_\tau^{(\infty)})$ is exponentially decreasing. If $R > \text{dis}(x_0, \partial\Omega)$. Then in view of Theorem 1.1 (4), (2.20) and (2.21), we see that $(Tf_\tau^{(\infty)}, f_\tau^{(\infty)})$ is exponentially increasing. If $R = \text{dis}(x_0, \partial\Omega)$, by virtue of Theorem 1.2, (2.20) and (2.21), Theorem 1.2 holds with f_τ replaced by $f_\tau^{(\infty)}$. □

3 Computational methods

In this section we introduce a computational framework for practical testing of our theoretical results. The framework will be put into use in section 4.

3.1 Simulation of data

Recalling that our domain Ω must be away from the horizontal line $\{x_2 = 0\}$, we take Ω to be the square

$$(3.1) \quad \Omega = \{(x_1, x_2) : -1 \leq x_1 \leq 1, \quad \varepsilon \leq x_2 \leq 2 + \varepsilon\} \subset \mathbb{R}^2,$$

$\varepsilon > 0$ being a small constant, and denote the bottom boundary of Ω by Γ :

$$(3.2) \quad \Gamma = \{(x_1, \varepsilon) : -1 < x_1 < 1\}.$$

FIGURE 3.1. Two examples of our tailored FEM meshes. We refine the mesh near Γ to allow numerical differentiation of the solution on Γ to evaluate the DN map. The mesh has $2^M + 1$ nodes on the top boundary and $2^N + 1$ nodes on the bottom boundary. Left: the mesh with $M = 2$ and $N = 5$. Right: $M = 4$ and $N = 8$. In our actual computations we use $M = 6$ and $N = 12$.

In all our numerical examples we assume that the background conductivity is constant: $\gamma_0 \equiv 1$. We assume that we can measure only on Γ and use the Dirichlet data

$$(3.3) \quad f_\tau \text{ on } \Gamma, \quad 0 \text{ on } \partial\Omega \setminus \Gamma.$$

Exponential decay of f_τ outside Γ ensures that the error caused by the truncation (3.3) is small.

For the computation of DN maps we use two approaches. First, for homogeneous and layered media we can represent the DN map exactly, as explained in Appendix A. Second, for general conductivities we use the Finite Element Method (FEM). We solve a given Dirichlet problem using a FEM mesh of the type depicted in Figure 3.1, and use finite differences to approximate the normal derivative of the solution on Γ . We validate our FEM code by comparing the results from the two approaches for simple examples with layered media.

We add noise to the simulated data as follows. Define a random function $\eta : [-1, 1] \rightarrow \mathbb{C}$ by

$$(3.4) \quad \eta(t) = \sum_{j=-32}^{32} (a_j + ib_j) e^{ijt\pi/2},$$

where $a_j, b_j \sim \mathcal{N}(0, 1)$ are normally distributed random numbers. The number 32 in (3.4) is chosen to roughly model a collection of 32 electrodes on the bottom boundary of Ω (the function $\exp(it32\pi/2)$ oscillates with the maximum frequency

that can be effectively approximated by 32 equidistant point values on Γ). Measurements noise is modelled by replacing Λf_τ by $\Lambda f_\tau + c\eta$ with noise amplitude

$$(3.5) \quad c := \frac{A \|\Lambda f_\tau\|_\infty}{\|\eta\|_\infty},$$

where $A > 0$ is suitably chosen.

3.2 Plan of detection

We cannot probe the whole square Ω by applying our method to measurements done on the bottom Γ . Let us define the maximal subset $Q_{\max} \subset \Omega$ available for sensing. For any point $x \in \mathbb{R}^2 \setminus \Omega$, define

$$R_{\max}(x) := \sup\{R \geq 0 \mid \overline{B(x, R)} \cap \partial\Omega \subset \Gamma\}.$$

The number $R_{\max}(x)$ gives the radius of the maximal disc centered at x ensuring that Dirichlet data supported in $B(x, R_{\max}(x)) \cap \partial\Omega$ is also supported in Γ . Set

$$(3.6) \quad Q_{\max} := \bigcup_{x \in \Gamma} (B(x, R_{\max}(x)) \cap \Omega).$$

Of course, in Theorem 1.1 the center of the sensing disc must be chosen from outside of $\overline{\Omega}$, and thus we cannot use the discs $B(x, R_{\max}(x))$ with $x \in \Gamma$. However, we can choose a point $\tilde{x} \in \mathbb{R}^2 \setminus \overline{\Omega}$ arbitrarily close to x and use Theorem 1.1 to check whether the disc $B(\tilde{x}, R_{\max}(\tilde{x}))$ intersects the inclusion or not. The set Q_{\max} is the limit case.

Further, given an inclusion $\Omega_1 \subset \subset \Omega$, let us define the largest region Q_{best} on which we can conclude the absence of inclusions by the measurements on Γ . Set

$$R_{\text{best}}(x) := \sup\{R \geq 0 \mid \overline{B(x, R)} \cap \partial\Omega \subset \Gamma, \overline{B(x, R)} \cap \overline{\Omega_1} = \emptyset\},$$

and define

$$(3.7) \quad Q_{\text{best}} := \bigcup_{x \in \Gamma} (B(x, R_{\text{best}}(x)) \cap \Omega).$$

Practical measurements are noisy, however, and we cannot expect to recover the set Q_{best} from measured data. In practice, reconstructions are computed using the following algorithm. Choose two parameters $\tau_1 < \tau_2$ and a finite set of points $x^{(j)} \in \mathbb{R}^2 \setminus \overline{\Omega}$ with $j = 1, 2, 3, \dots, J$. For each j choose a finite set of radii $0 < R(j, k) < R_{\max}(x^{(j)})$ for $k = 1, 2, 3, \dots, K$. Define inner products

$$(3.8) \quad I_1(j, k) := ((\Lambda - \Lambda_0)f_{\tau_1}, f_{\tau_1})_\Gamma \quad \text{and} \quad I_2(j, k) := ((\Lambda - \Lambda_0)f_{\tau_2}, f_{\tau_2})_\Gamma,$$

where $f_\tau = u_\tau|_{\partial\Omega}$ depends on $x^{(j)}$ and $R(j, k)$ through formulas (1.4) and (1.5). For each point $x^{(j)}$, define the largest disc not intersecting the inclusion by formula

$$(3.9) \quad R_{\text{rec}}(j) := \max_{1 \leq k \leq K} \{R(j, k) \mid I_1(j, k) \geq I_2(j, k)\}.$$

FIGURE 3.2. Examples of the Dirichlet data used in the detection algorithm with $\tau_1 = 1.5$ and $\tau_2 = 2.5$. Left column shows the choices of sensing discs. The plots in the right column show the corresponding Dirichlet data on Γ . Note the asymmetry of the functions with respect to the interval $B(x, R) \cap \Gamma$.

Then we can set

$$(3.10) \quad D_{\text{rec}} := \bigcup_{1 \leq j \leq J} \left(B(x^{(j)}, R_{\text{rec}}(j)) \cap \Omega \right),$$

and conclude that D_{rec} does not intersect the inclusion.

Remark that in Section 1.3 we describe the algorithm in the form that the center of the sensing disc is at the origin and the domain is translated in the upper half plane. Due to translation invariance the approach of this section is equivalent.

At this point we introduce an enhancement of the numerical reconstruction algorithm. Namely, as can be seen in Figure 3.2, the Dirichlet data f_τ defined using hyperbolic geometry is strongly asymmetric. So we expect the above algorithm to perform differently in practice according to the location of inclusions. (This expectation is confirmed by numerical experiments.) To overcome this problem we assume that the domain Ω is symmetric with respect to the x_2 -axis: $\Omega =$

$\{(x_1, x_2) \mid (-x_1, x_2) \in \Omega\}$. We define the set D'_{rec} similarly to D_{rec} above but corresponding to the reflected conductivity $\gamma'(x_1, x_2) := \gamma(-x_1, x_2)$. Then we denote

$$D''_{\text{rec}} := \{(x_1, x_2) \mid (-x_1, x_2) \in D'_{\text{rec}}\}$$

and define the symmetrized reconstruction as

$$(3.11) \quad Q_{\text{rec}} := D_{\text{rec}} \cup D''_{\text{rec}}.$$

Our final reconstruction result is that the set Q_{rec} does not intersect the inclusion.

We use the following quantity for measuring relative error of reconstructions:

$$(3.12) \quad \frac{\mu(Q_{\text{best}} \setminus Q_{\text{rec}}) + \mu(Q_{\text{rec}} \setminus Q_{\text{best}})}{\mu(Q_{\text{best}})} \cdot 100\%,$$

where μ stands for area (Lebesgue measure in \mathbb{R}^2).

4 Numerical results

4.1 Layered medium

Let $\sigma = 4$ and $0 < h < 2$. Take Ω as in (3.1) with $\varepsilon = 0.2$ and define a discontinuous conductivity γ on Ω :

$$(4.1) \quad \gamma(x_1, x_2) = \begin{cases} \sigma & \text{for } x_2 > h + \varepsilon, \\ 1 & \text{for } x_2 \leq h + \varepsilon. \end{cases}$$

Here γ models a material with two layers of different conductivities divided by an interface at $x_2 = h + \varepsilon$.

In this simple situation the conductivity is completely characterized by one real number, namely the interface position h . In the case $h < R_{\text{max}}(0) - \varepsilon$, it is enough to know $R_{\text{best}}(0)$. We study our detection algorithm by recovering $R_{\text{rec}}(0)$ from measured data corresponding to several choices of h and computing the relative error

$$(4.2) \quad \frac{|R_{\text{best}}(0) - R_{\text{rec}}(0)|}{R_{\text{best}}(0)} \cdot 100\%.$$

Figure 4.1(a) illustrates the geometry of our setup: for fixed interface h , we take several discs with center at the origin and varying radii.

We take $\tau_1 = 1.5$ and $\tau_2 = 2.5$ and compute the inner products (3.8) using trapezoidal rule. See Figure 4.2 for the results.

To ensure that our FEM-based solver is correct, we compare the numerical normal derivatives to the ones calculated using the exact eigenvalues of DN maps given in Appendix A. The relative $L^\infty([-1, 1])$ difference between normal derivatives computed with the two methods is less than 0.1% for a representative set of layered conductivities and for sinusoidal Dirichlet data within relevant frequency range. We conclude that we can trust our FEM code.

Next we introduce noise in the data. We choose $A = 0.0001$ in formula (3.5); this corresponds to 0.01% noise level. Reconstructions are shown in Figure 4.2.

FIGURE 4.1. Collection of discs for probing the square domain. Black dots denote centers of discs. (a) Discs for probing layered media. The maximal disc $B(0, R_{\text{best}}(0))$ that touches the upper layer is drawn with thick line. (b) Discs for probing inclusions.

4.2 Inclusions in homogeneous background

We choose test conductivities having inclusions in homogeneous background. We again take the background conductivity to equal 1, and the inclusions are chosen to be various geometrical shapes with conductivity 4. The example conductivities are shown in the left column of Figure 4.3.

Figure 4.1(b) shows one possible collection of discs for probing the domain. We use somewhat more discs than shown in Figure 4.1(b). See Figure 4.3 for reconstructions from ideal and noisy data. The percentages are given by formula (3.12).

5 Conclusion

We present a novel algorithm for detecting inclusions in known background conductivity from localized boundary measurements. Our method allows (partial) recovery of concave features of inclusions since we use spheres to probe the unknown medium. We justify the algorithm theoretically using hyperbolic geometry. While the numerical examples in this paper are two-dimensional, the algorithm is applicable in three-dimensional situations as well.

Although the reconstruction Theorem 1.1 holds only asymptotically for large enough τ , for practical reasons we must take $\tau < 3$. Namely, using large values of τ would require the application of Dirichlet data with impractical amplitude and frequency of spatial oscillation. However, we achieve useful reconstructions that

- (1) use Dirichlet data suitable for practical electrode measurements,
- (2) are robust against measurement noise, and
- (3) require very little computational effort (in particular, our method is not iterative and no direct problems need to be solved).

Our numerical studies suggest that inclusions relatively close to the boundary can be detected even from noisy data. However, we cannot probe reliably very deep

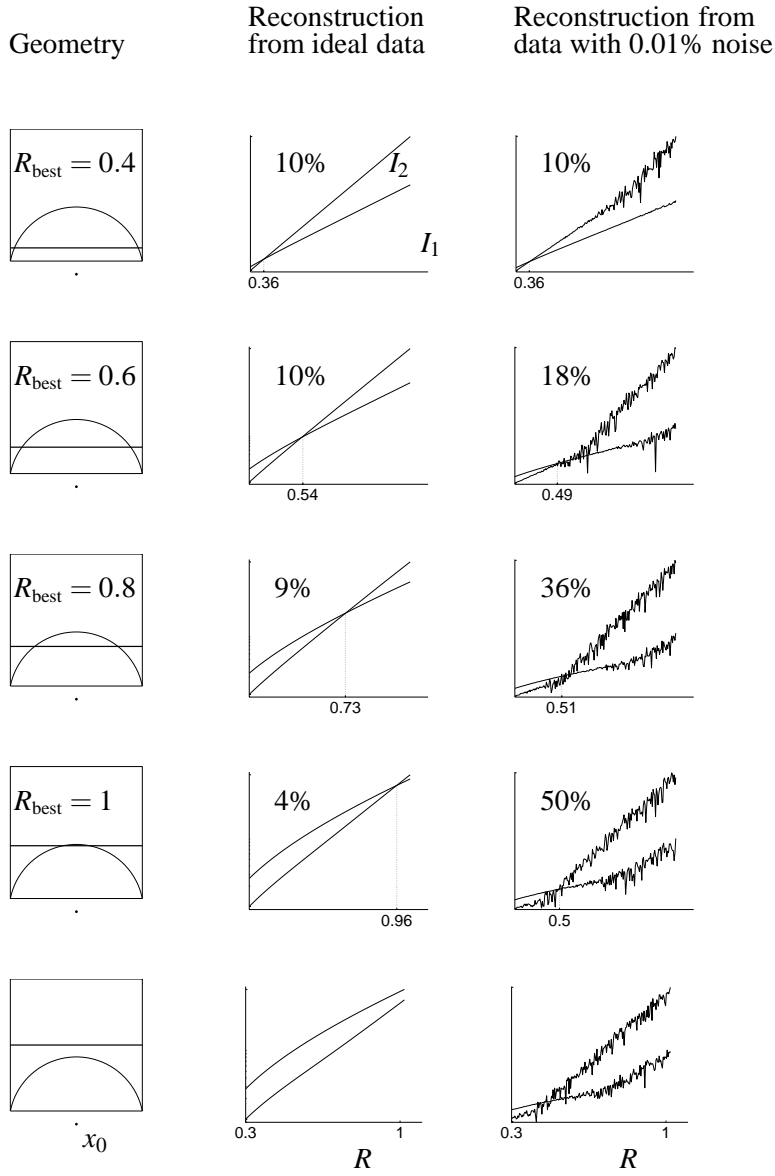

FIGURE 4.2. Left column: Geometry of layered medium examples. Thick horizontal line indicates the interface between two layers with different conductivity. $R_{\text{best}} = R_{\text{best}}(0)$ denotes the radius of the largest sensing disc that does not intersect the upper conductivity layer. Middle column: The logarithms of inner products I_1 and I_2 are plotted as functions of R . The percentage gives relative error (4.2). Right column: same plots than in middle column except that noise is added to the simulated measurements.

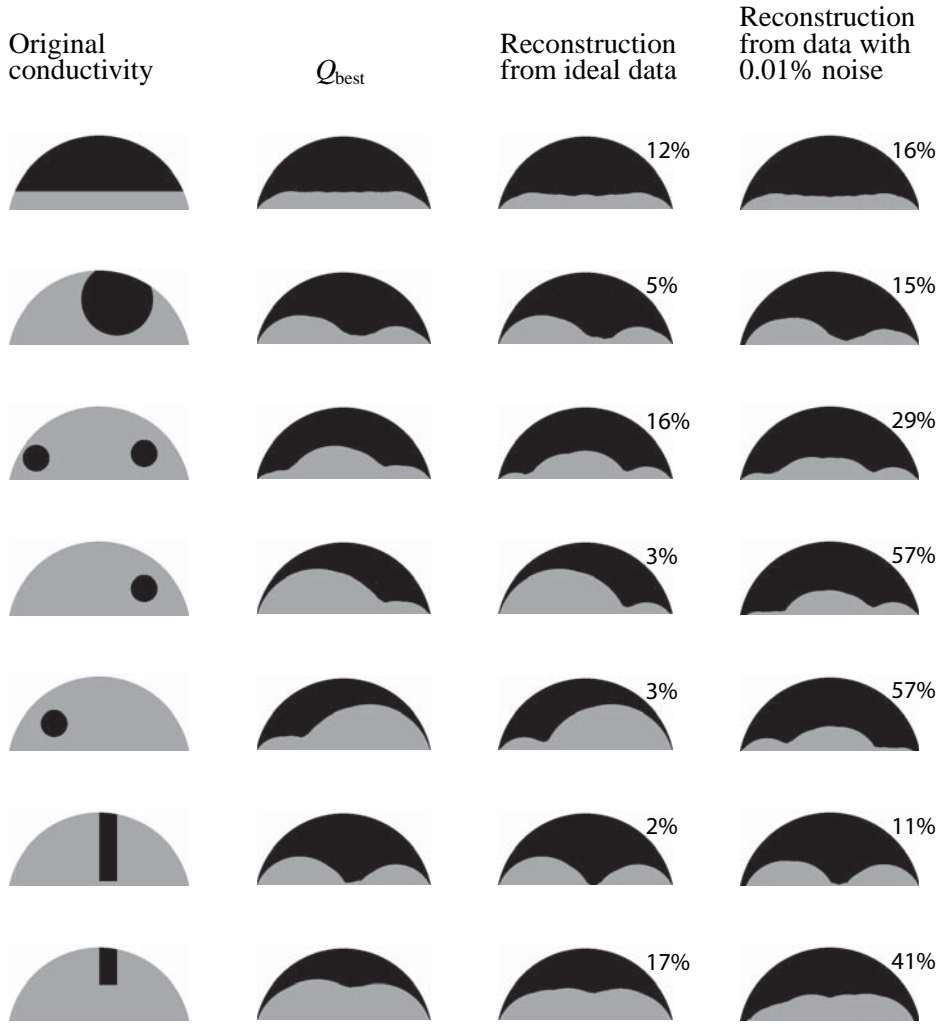

FIGURE 4.3. Each row of images demonstrates reconstructions of an example conductivity containing inclusions. All functions are plotted only inside the maximal set Q_{max} as defined in (3.6), rather than in the full square domain Ω . First column: true conductivity. Gray is homogeneous background, black is inclusion. Second column: the largest region Q_{best} on which we can conclude the absence of inclusions by the measurements on Γ , see (3.7). Third column: the set Q_{rec} as defined in (3.11) reconstructed from simulated boundary data with no noise. The percentage is the relative error defined in (3.12). Fourth column: the same as third column but computed using noisy simulated boundary data.

into the unknown medium. This is in accordance with the usual intuition about EIT: details in conductivity that are far away from the boundary are more difficult to recover than details near the boundary.

Our method finds applications in medical imaging, industrial process monitoring and nondestructive testing.

Appendix: Exact DN map for layered medium in dimension two

A.1 DN map for homogeneous conductivity

Let Ω and Γ be given by (3.1) and (3.2), respectively, with $\varepsilon = 0$. We want to solve the Dirichlet problem

$$(A.1) \quad \begin{cases} \Delta u = 0 & \text{in } \Omega, \\ u = \varphi_k & \text{on } \Gamma, \\ u = 0 & \text{on } \partial\Omega \setminus \Gamma, \end{cases}$$

where $\varphi_k(x_1) = \sin(k\pi(x_1 + 1)/2)$ for $-1 \leq x_1 \leq 1$ and $k \in \mathbb{Z}$. We use the ansatz

$$(A.2) \quad u(x_1, x_2) = \left[A \exp\left(\frac{k\pi}{2}x_2\right) + B \exp\left(-\frac{k\pi}{2}x_2\right) \right] \sin\left(\frac{k\pi}{2}(x_1 + 1)\right).$$

Now at the interval specified by $x_2 = 2$ and $-1 \leq x_1 \leq 1$ the function u must vanish, leading to $A \exp(k\pi) + B \exp(-k\pi) = 0$. Further, $u|_{\Gamma} = \varphi_k$ gives $A + B = 1$. Thus

$$A = \frac{1}{1 - e^{2k\pi}}, \quad B = -\frac{e^{2k\pi}}{1 - e^{2k\pi}}.$$

The functions φ_k are eigenfunctions for Λ_0 :

$$\Lambda_0 \varphi_k = -\frac{\partial u}{\partial x_2} \Big|_{x_2=0} = -\frac{k\pi}{2}(B - A)\varphi_k = k\pi \left(\frac{1 + e^{-2k\pi}}{1 - e^{-2k\pi}} \right) \varphi_k.$$

A.2 DN map for layered medium

We want to solve

$$(A.3) \quad \begin{cases} \nabla \cdot (\gamma \nabla v) = 0 & \text{in } \Omega, \\ v = \varphi_k & \text{on } \Gamma, \\ v = 0 & \text{on } \partial\Omega \setminus \Gamma, \end{cases}$$

where γ is defined by (4.1) with $\varepsilon = 0$. The solution v is harmonic in the open sets $\Omega \cap \{x_2 > h\}$ and $\Omega \cap \{x_2 < h\}$, and both v and $\gamma(\partial v / \partial n)$ are continuous at the interface.

We will solve (A.3) with the ansatz

$$v(x_1, x_2) = \begin{cases} \left[C \exp\left(\frac{k\pi}{2}x_2\right) + D \exp\left(-\frac{k\pi}{2}x_2\right) \right] \sin\left(\frac{k\pi}{2}(x_1 + 1)\right) & \text{for } x_2 \geq h, \\ \left[E \exp\left(\frac{k\pi}{2}x_2\right) + F \exp\left(-\frac{k\pi}{2}x_2\right) \right] \sin\left(\frac{k\pi}{2}(x_1 + 1)\right) & \text{for } x_2 < h. \end{cases}$$

At the interval specified by $x_2 = 2$ and $-1 \leq x_1 \leq 1$ the function v must vanish, giving $C \exp(k\pi) + D \exp(-k\pi) = 0$. Continuity of v at the interface yields

$$C \exp\left(\frac{k\pi h}{2}\right) + D \exp\left(-\frac{k\pi h}{2}\right) = E \exp\left(\frac{k\pi h}{2}\right) + F \exp\left(-\frac{k\pi h}{2}\right),$$

and continuity of $\gamma(\partial v / \partial n)$ at the interface gives

$$\sigma C \exp\left(\frac{k\pi h}{2}\right) - \sigma D \exp\left(-\frac{k\pi h}{2}\right) = E \exp\left(\frac{k\pi h}{2}\right) - F \exp\left(-\frac{k\pi h}{2}\right).$$

The condition $v|_{\Gamma} = \varphi_k$ leads to $F = 1 - E$. Finally, we get $D = -C \exp(2k\pi)$ and

$$C = \frac{e^{-k\pi h}}{(1 + e^{-k\pi h})(1 - e^{k\pi(2-h)}) - \sigma(1 - e^{-k\pi h})(1 + e^{k\pi(2-h)})},$$

$$E = \frac{e^{-k\pi h} \{ \sigma(1 + e^{k\pi(2-h)}) - (1 - e^{k\pi(2-h)}) \}}{2 \{ \sigma(1 - e^{-k\pi h})(1 + e^{k\pi(2-h)}) + (1 + e^{-k\pi h})(1 - e^{k\pi(2-h)}) \}}.$$

The functions φ_k are eigenfunctions for Λ :

$$\Lambda \varphi_k = -\frac{\partial v}{\partial x_2} \Big|_{x_2=0} = -\frac{k\pi}{2}(E - F)\varphi_k = \frac{k\pi}{2} \left(\frac{1}{2} - 2E \right) \varphi_k.$$

Acknowledgment.

The authors thank Masaru Ikehata and David Isaacson for their valuable comments, and also the referee whose excellent advice brought a considerable improvement of the paper.
